INTRODUCTION: Calcium phosphates, including hydroxyapatite (HAP) have been paid attention of intensive research as bone filler, bone graft substitutes do to its biocompatibility and osteo-conduction. The main results of investigations of HAP materials performed in frames of EUREKA project E!3033 BIONANOCOMPOSIT (in period of 2003-2012) are shortly summarised in this report.

METHODS: The chemical interaction between calcium hydroxide and phosphoric acid was chosen for synthesis of the HAP nanopowder. Various methods for manufacturing dense HAP materials from obtained powders were used and compared (Table 1). Biocompatibility was compared by enumeration of the number of osteoblast-like cells to the materials.

RESULTS: The TEM image (Fig. 1) of the synthesized HAP nanopowder shows the agglomerate which consist of nanosized rod-shaped particles in size of 50–100 nm. The powder obtained by spray-drying consisted from quasi spherical granules with average diameter of 20-40 μm.

Table 1. Sintering conditions for production HAP materials with relative density > 95 % and the average grain size of the obtained material.

The specific surface area of such powder was in the range of 60-70 m²/g. The XRD pattern of the powder showed low crystallinity. The only peaks recognized were those corresponding to the calcium hydroxyapatite phase (JCPDS pattern 9–432 for HAP).
